

# Options on Stock Indices, Currencies, and Futures

In this chapter we tackle the problem of valuing options on stock indices, currencies, and futures contracts. As a first step, we produce results for options on a stock paying a known dividend yield. We then argue that stock indices, currencies, and futures prices are analogous to stocks paying known dividend yield. This enables the results for options on a stock paying a dividend yield to be applied to value options on these other assets.

#### 14.1 RESULTS FOR A STOCK PAYING A KNOWN DIVIDEND YIELD

This section provides a simple rule that enables results produced for European options on a non-dividend-paying stock to be extended so that they apply to European options on a stock paying a known dividend yield.

Dividends cause stock prices to reduce on the ex-dividend date by the amount of the dividend payment. The payment of a dividend yield at rate q therefore causes the growth rate in the stock price to be less than it would otherwise be by an amount q. If, with a dividend yield of q, the stock price grows from  $S_0$  today to  $S_T$  at time T, then in the absence of dividends it would grow from  $S_0$  today to  $S_Te^{qT}$  at time T. Alternatively, in the absence of dividends, it would grow from  $S_0e^{-qT}$  today to  $S_T$  at time T.

This argument shows that we get the same probability distribution for the stock price at time T in each of the following two cases:

- 1. The stock starts at price  $S_0$  and provides a dividend yield at rate q.
- 2. The stock starts at price  $S_0e^{-qT}$  and pays no dividends.

This leads to a simple rule. When valuing a European option lasting for time T on a stock paying a known dividend yield at rate q, we reduce the current stock price from  $S_0$  to  $S_0e^{-qT}$  and then value the option as though the stock pays no dividends.

## **Lower Bounds for Option Prices**

As a first application of this rule, consider the problem of determining bounds for the price of a European option on a stock providing a dividend yield equal to q. Substituting  $S_0e^{-qT}$  for  $S_0$  in equation (9.1), we see that the lower bound for the European call option price c is

 $c \geqslant \max(S_0 e^{-qT} - K e^{-rT}, 0)$  (14.1)

To obtain a lower bound for a European put option, we can similarly replace  $S_0$  by  $S_0e^{-qT}$  in equation (9.2), to get

$$p \ge \max(Ke^{-rT} - S_0e^{-qT}, 0)$$
 (14.2)

These results can also be proved using no-arbitrage arguments (see Problem 14.36).

## **Put-Call Parity**

Replacing  $S_0$  by  $S_0e^{-qT}$  in equation (9.3), we obtain put-call parity for a stock providing a dividend yield equal to q:

 $c + Ke^{-rT} = p + S_0 e^{-qT} (14.3)$ 

This result can also be proved using no-arbitrage arguments (see Problem 14.36).

## 14.2 OPTION PRICING FORMULAS

By replacing  $S_0$  by  $S_0e^{-qT}$  in the Black-Scholes formulas, equations (13.20) and (13.21), we obtain the price c of a European call and the price p of a European put on a stock providing a dividend yield at rate q as

$$c = S_0 e^{-qT} N(d_1) - K e^{-rT} N(d_2)$$
(14.4)

$$p = Ke^{-rT}N(-d_2) - S_0e^{-qT}N(-d_1)$$
(14.5)

Since

$$\ln\left(\frac{S_0 e^{-qT}}{K}\right) = \ln\frac{S_0}{K} - qT$$

the parameters  $d_1$  and  $d_2$  are given by

$$\begin{aligned} d_1 &= \frac{\ln(S_0/K) + (r - q + \sigma^2/2)T}{\sigma\sqrt{T}} \\ d_2 &= \frac{\ln(S_0/K) + (r - q - \sigma^2/2)T}{\sigma\sqrt{T}} = d_1 - \sigma\sqrt{T} \end{aligned}$$

These results were first derived by Merton. As discussed in Section 13.12, the word "dividend" should be defined as the reduction of the stock price on the ex-dividend date arising from any dividends declared. If the dividend yield is not constant during the life of the option, equations (14.4) and (14.5) are still true, with q equal to the average

<sup>&</sup>lt;sup>1</sup> See R. Merton, "Theory of Rational Option Pricing," *Bell Journal of Economics and Management Science*, 4 (Spring 1973): 141-83.

annualized dividend yield during the life of the option. The dividend yield should be expressed with continuous compounding (see Section 5.6).

## Differential Equation and Risk-Neutral Valuation

To prove the results in equations (14.4) and (14.5) more formally, we can either solve the differential equation that the option price must satisfy or use risk-neutral valuation.

When we include a dividend yield of q in the analysis in Section 13.6, the differential equation (13.16) becomes<sup>2</sup>

$$\frac{\partial f}{\partial t} + (r - q)S\frac{\partial f}{\partial S} + \frac{1}{2}\sigma^2 S^2 \frac{\partial^2 f}{\partial S^2} = rf$$
 (14.6)

Like equation (13.16), this does not involve any variable affected by risk preferences. Therefore, the risk-neutral valuation procedure, described in Section 13.7, can be used.

In a risk-neutral world, the total return from the stock must be r. The dividends provide a return of q. The expected growth rate in the stock price must therefore be r-q. So the risk-neutral process for the stock price is given by

$$dS = (r - q)S dt + \sigma S dz$$
 (14.7)

To value a derivative dependent on a stock that provides a dividend yield equal to q, we set the expected growth rate of the stock equal to r-q and discount the expected payoff at rate r. When the expected growth rate in the stock price is r-q, the expected stock price at time T is  $S_0e^{(r-q)T}$ . A similar analysis to that in the appendix of Chapter 13 gives the expected payoff in a risk-neutral world as

$$e^{(r-q)T}S_0N(d_1) - KN(d_2)$$

where  $d_1$  and  $d_2$  are defined as above. Discounting at rate r for time T leads to equation (14.4).

#### **Binomial Trees**

Binomial trees can be used to value an option on a stock paying a known dividend yield in the way described in Chapter 11. To match the stock price volatility, we set

$$u = e^{\sigma\sqrt{\Delta t}}$$
 and  $d = e^{-\sigma\sqrt{\Delta t}}$ 

where  $\Delta t$  is the length of the time step. The risk-neutral probability p of an up movement is chosen so that the expected return is r-q. This means that

$$pSu + (1-p)Sd = e^{(r-q)\Delta t}$$
$$p = \frac{a-d}{u-d}$$

 $a = e^{(r-q)\Delta t}$ 

or

where

This was the result we used in Section 11.9.

<sup>&</sup>lt;sup>2</sup> See Technical Note 6 on the author's website for a proof of this.

#### 14.3 OPTIONS ON STOCK INDICES

As discussed in Chapter 8, several exchanges trade options on stock indices. Some of the indices track the movement of the market as a whole. Others are based on the performance of a particular sector (e.g., computer technology, oil and gas, transportation, or telecommunications).

## Quotes

Table 14.1 shows quotes for options on the Dow Jones Industrial Average (DJX) and S&P 500 (SPX) as they appeared in the Money and Investing section of the Wall Street

Journal on Thursday February 5, 2004. The Wall Street Journal also shows quotes for options on a number of other indices including the Nasdaq 100 (NDX), Russell 2000 (RUT), and S&P 100 (OEX). All the options trade on the Chicago Board Options Exchange and all are European, except the contract on the S&P 100, which is American. The quotes refer to the price at which the last trade was made on Wednesday, February 4, 2004. The closing prices of the DJX and SPX on February 4, 2004, were 104.71 and 1,126.52, respectively.

One index option contract is on 100 times the index. (Note that the Dow Jones index used for index options is 0.01 times the usually quoted Dow Jones index.) Index options are settled in cash. This means that, on exercise of the option, the holder of a call option contract receives  $(S - K) \times 100$  in cash and the writer of the contract pays this amount in cash, where S is the value of the index at the close of trading on the day of the exercise and K is the strike price. Similarly, the holder of a put option contract receives  $(K - S) \times 100$  in cash and the writer of the contract pays this amount in cash.

Table 14.1 shows that, in addition to relatively short-dated options, the exchanges trade longer-maturity contracts known as LEAPS. The acronym LEAPS stands for "long-term equity anticipation securities" and was originated by the CBOE. LEAPS are exchange-traded options that last up to 3 years. (Note when interpreting Table 14.1 that the S&P 500 index is divided by 10 for the purpose of defining LEAPS contracts.) The usual expiration month for LEAPS on indices is December. As mentioned in Chapter 8, the CBOE and several other exchanges also trade LEAPS on many individual stocks. These have expirations in January.

The CBOE also trades *flex options* on indices. As mentioned in Chapter 8, these are options where the trader can choose the expiration date, the strike price, and whether the option is American or European.

#### Valuation

In valuing index futures in Chapter 5, we assumed that the index could be treated as a security paying a known dividend yield. In valuing index options, we make similar assumptions. This means that equations (14.1) and (14.2) provide a lower bound for European index options; equation (14.3) is the put—call parity result for European index options; and equations (14.4) and (14.5) can be used to value European options on an index. In all cases,  $S_0$  is equal to the value of the index,  $\sigma$  is equal to the volatility of the index, and q is equal to the average annualized dividend yield (continuously compounded) on the index during the life of the option. The calculation of q should include only dividends whose ex-dividend date occurs during the life of the option.

In the United States ex-dividend dates tend to occur during the first week of February, May, August, and November. At any given time, the correct value of q is therefore likely to depend on the life of the option. This is even more true for some foreign indices. In Japan, for example, all companies tend to use the same ex-dividend dates.

#### Example 14.1

Consider a European call option on the S&P 500 that is 2 months from maturity. The current value of the index is 930, the exercise price is 900, the risk-free interest rate is 8% per annum, and the volatility of the index is 20% per annum. Dividend yields of 0.2% and 0.3% are expected in the first month and the second month,

respectively. In this case,  $S_0 = 930$ , K = 900, r = 0.08,  $\sigma = 0.2$ , and T = 2/12. The total dividend yield during the option's life is 0.2 + 0.3 = 0.5%. This is 3% per annum. Hence, q = 0.03, and

$$d_1 = \frac{\ln(930/900) + (0.08 - 0.03 + 0.2^2/2) \times 2/12}{0.2\sqrt{2/12}} = 0.5444$$

$$d_2 = \frac{\ln(930/900) + (0.08 - 0.03 - 0.2^2/2) \times 2/12}{0.2\sqrt{2/12}} = 0.4628$$

$$N(d_1) = 0.7069, \qquad N(d_2) = 0.6782$$

so that the call price c is given by equation (14.4) as

$$c = 930 \times 0.7069e^{-0.03 \times 2/12} - 900 \times 0.6782e^{-0.08 \times 2/12} = 51.83$$

One contract would cost \$5,183.

If the absolute amount of the dividend that will be paid on the stocks underlying the index (rather than the dividend yield) is assumed to be known, the basic Black—Scholes formula can be used with the initial stock price being reduced by the present value of the dividends. This is the approach recommended in Chapter 13 for a stock paying known dividends. However, it may be difficult to implement for a broadly based stock index because it requires a knowledge of the dividends expected on every stock underlying the index.

#### **Binomial Trees**

In some circumstances it is optimal to exercise American put and call options on an index prior to the expiration date. Binomial trees can be used to value American-style index options as discussed in Section 11.9. An example of the use of binomial trees for index options is in Example 11.1 and Figure 11.11.

#### Portfolio Insurance

Portfolio managers can use index options to limit their downside risk. Suppose that the value of an index today is  $S_0$ . Consider a manager in charge of a well-diversified portfolio whose beta is 1.0. A beta of 1.0 implies that the returns from the portfolio mirror those from the index. Assuming the dividend yield from the portfolio is the same as the dividend yield from the index, the percentage changes in the value of the portfolio can be expected to be approximately the same as the percentage changes in the value of the index. Each contract on the S&P 500 is on 100 times the index. It follows that the value of the portfolio is protected against the possibility of the index falling below K if, for each  $100S_0$  dollars in the portfolio, the manager buys one put option contract with strike price K. Suppose that the manager's portfolio is worth \$500,000 and the value of the index is 1,000. The portfolio is worth 500 times the index. The manager can obtain insurance against the value of the portfolio dropping below \$450,000 in the next 3 months by buying five put option contracts with a strike price

## Business Snapshot 14.1 Can We Guarantee that Stocks Will Beat Bonds in the Long Run?

It is often said that if you are a long-term investor you should buy stocks rather than bonds. Consider a US fund manager who is trying to persuade investors to buy as a long-term investment an equity fund that is expected to mirror the S&P 500. The manager might be tempted to offer purchasers of the fund a guarantee that their return will be at least as good as the return on risk-free bonds over the next 10 years. Historically stocks have outperformed bonds in the United States over almost any 10-year period. It appears that the fund manager would not be giving much away.

In fact, this type of guarantee is surprisingly expensive. Suppose that an equity index is 1,000 today, the dividend yield on the index is 1% per annum, the volatility of the index is 15% per annum, and the 10-year risk-free rate is 5% per annum. To outperform bonds, the stocks underlying the index must earn more than 5% per annum. The dividend yield will provide 1% per annum. The capital gains on the stocks must therefore provide 4% per annum. This means that we require the index level to be at least  $1,000e^{0.04\times10}=1,492$  in 10 years.

A guarantee that the return on \$1,000 invested in the index will be greater than the return on \$1,000 invested in bonds over the next 10 years is therefore equivalent to the right to sell the index for 1,492 in 10 years. This is a European put option on the index and can be valued from equation (14.5) with  $S_0 = 1,000$ , K = 1,492, r = 5%,  $\sigma = 15\%$ , T = 10, and q = 1%. The value of the put option is 169.7. This shows that the guarantee contemplated by the fund manager is worth about 17% of the fund—hardly something that should be given away!

of 900. Suppose that the risk-free rate is 12%, the dividend yield on the index is 4%, and the volatility of the index is 22%. The parameters of the option are:

$$S_0 = 1000$$
,  $K = 900$ ,  $r = 0.12$ ,  $\sigma = 0.22$ ,  $T = 0.25$ ,  $q = 0.04$ 

From equation (14.5), the value of the option is \$6.48. The cost of the insurance is therefore  $5 \times 100 \times 6.48 = \$3,240$ .

To illustrate how the insurance works, consider the situation where the index drops to 880 in 3 months. The portfolio will be worth about \$440,000. The payoff from the options will be  $5 \times (900 - 880) \times 100 = \$10,000$ , bringing the total value of the portfolio up to the insured value of \$450,000 (or \$446,760 when the cost of the options are taken into account).

It is sometimes argued that the return from stocks is certain to beat the return from bonds in the long run. If this were true, long-dated portfolio insurance where the strike price equaled the future value of a bond portfolio would not cost very much. In fact, as indicated in Business Snapshot 14.1, it is quite expensive.

## When the Portfolio's Beta Is Not 1.0

If the portfolio's returns are not expected to equal those of an index, the capital asset pricing model can be used. This model asserts that the expected excess return of a portfolio over the risk-free interest rate equals beta times the excess return of a market index over the risk-free interest rate. Suppose that the \$500,000 portfolio just considered

<b>Table 14.2</b>	Relationship between value of index
and value	of portfolio for beta $= 2.0$ .

Value of index in 3 months	Value of portfolio in 3 months (\$)
1,080	570,000
1,040	530,000
1,000	490,000
960、	450,000
920	410,000
880	370,000

has a beta of 2.0 instead of 1.0. As before, we assume that the S&P 500 index is currently 1,000, the risk-free rate is 12% and the dividend yield on the index is 4%. Table 14.2 shows the expected relationship between the level of the index and the value of the portfolio in 3 months. To illustrate the sequence of calculations necessary to derive Table 14.2, Table 14.3 shows the calculations for the case when the value of the index in 3 months proves to be 1,040.

Suppose that  $S_0$  is the value of the index. It can be shown that, for each  $100S_0$  dollars in the portfolio, a total of beta put contracts should be purchased. The strike price should be the value that the index is expected to have when the value of the portfolio reaches the insured value. Assume that the required insured value is \$450,000, as in the beta = 1.0 case. Table 14.2 shows that the appropriate strike price for the put options purchased is 960. The option parameters are:

$$S = 1000$$
,  $K = 960$ ,  $r = 0.12$ ,  $\sigma = 0.22$ ,  $T = 0.25$ ,  $q = 0.04$ 

and equation (14.5) gives the value of the option as \$19.21. In this case,  $100S_0 = $100,000$  and beta = 2.0, so that two put contracts are required for each \$100,000 in the portfolio.

**Table 14.3** Calculations for Table 14.2 when the value of the index is 1,040 in 3 months.

Value of index in 3 months: Return from change in index:	1,040 40/1,000, or 4% per 3 months
Dividends from index:	$0.25 \times 4 = 1\%$ per 3 months
Total return from index:	4 + 1 = 5% per 3 months
Risk-free interest rate:	$0.25 \times 12 = 3\%$ per 3 months
Excess return from index	
over risk-free interest rate:	5-3=2% per 3 months
Excess return from portfolio	
over risk-free interest rate:	$2 \times 2 = 4\%$ per 3 months
Return from portfolio:	3+4=7% per 3 months
Dividends from portfolio:	$0.25 \times 4 = 1\%$ per 3 months
Increase in value of portfolio:	7 - 1 = 6% per 3 months
Value of portfolio:	$$500,000 \times 1.06 = $530,000$

Since the portfolio is worth \$500,000, a total of 10 contracts should be purchased. The total cost of the insurance is therefore  $10 \times 100 \times 19.21 = $19,210$ .

To illustrate that the required result is obtained, consider what happens if the value of the index falls to 880. As shown in Table 14.2, the value of the portfolio is then about \$370,000. The put options pay off  $(960 - 880) \times 10 \times 100 = \$80,000$ , and this is exactly what is necessary to move the total value of the portfolio manager's position up from \$370,000 to the required level of \$450,000. (After the cost of the options are taken into account the value of the portfolio is \$430,790.)

There are two reasons why the cost of hedging increases as the beta of a portfolio increases: more put options are required, and they have a higher strike price.

#### 14.4 CURRENCY OPTIONS

Currency options are primarily traded in the over-the-counter market. The advantage of this market is that large trades are possible with strike prices, expiration dates, and other features tailored to meet the needs of corporate treasurers. European and American options do trade on the Philadelphia Stock Exchange in the United States, but the exchange-traded market is much smaller than the over-the-counter market.

For a corporation wishing to hedge a foreign exchange exposure, foreign currency options are an interesting alternative to forward contracts. A company due to receive sterling at a known time in the future can hedge its risk by buying put options on sterling that mature at that time. The strategy guarantees that the value of the sterling will not be less than the strike price, while allowing the company to benefit from any favorable exchange-rate movements. Similarly, a company due to pay sterling at a known time in the future can hedge by buying calls on sterling that mature at that time. The approach guarantees that the cost of the sterling will not be greater than a certain amount while allowing the company to benefit from favorable exchange-rate movements. Whereas a forward contract locks in the exchange rate for a future transaction, an option provides a type of insurance. This insurance is not free. It costs nothing to enter into a forward transaction, whereas options require a premium to be paid up front.

#### **Valuation**

To value currency options, we define  $S_0$  as the spot exchange rate. To be precise,  $S_0$  is the value of one unit of the foreign currency in US dollars. As explained in Section 5.10, a foreign currency is analogous to a stock paying a known dividend yield. The owner of foreign currency receives a yield equal to the risk-free interest rate,  $r_f$ , in the foreign currency. Equations (14.1) and (14.2), with q replaced by  $r_f$ , provide bounds for the European call price, c, and the European put price, p:

$$c \geqslant S_0 e^{-r_f T} - K e^{-rT}$$
$$p \geqslant K e^{-rT} - S_0 e^{-r_f T}$$

Equation (14.3), with q replaced by  $r_f$ , provides the put–call parity result for currency options:

 $c + Ke^{-rT} = p + S_0e^{-r_fT}$ 

Finally, equations (14.4) and (14.5) provide the pricing formulas for currency options when q is replaced by  $r_f$ :

$$c = S_0 e^{-r_f T} N(d_1) - K e^{-rT} N(d_2)$$
(14.7)

$$p = Ke^{-rT}N(-d_2) - S_0e^{-r_fT}N(-d_1)$$
(14.8)

where

$$d_1 = \frac{\ln(S_0/K) + (r - r_f + \sigma^2/2)T}{\sigma\sqrt{T}}$$

$$d_2 = \frac{\ln(S_0/K) + (r - r_f - \sigma^2/2)T}{\sigma\sqrt{T}} = d_1 - \sigma\sqrt{T}$$

Both the domestic interest rate, r, and the foreign interest rate,  $r_f$ , are the rates for a maturity T. Put and call options on a currency are symmetrical in that a put option to sell currency A for currency B at an exercise price K is the same as a call option to buy B with A at 1/K.

#### Example 14.2

Consider a 4-month European call option on the British pound. Suppose that the current exchange rate is 1.6000, the exercise price is 1.6000, the risk-free interest rate in the United States is 8% per annum, the risk-free interest rate in Britain is 11% per annum, and the option price is 4.3 cents. In this case,  $S_0 = 1.6$ , K = 1.6, r = 0.08,  $r_f = 0.11$ , T = 0.3333, and c = 0.043. The implied volatility can be calculated by trial and error. A volatility of 20% gives an option price of 0.0639, a volatility of 10% gives an option price of 0.0285, and so on. The implied volatility is 14.1%.

From equation (5.9), the forward rate  $F_0$  for a maturity T is given by

$$F_0 = S_0 e^{(r-r_f)T}$$

Thus, equations (14.7) and (14.8) can be simplified to

$$c = e^{-rT}[F_0N(d_1) - KN(d_2)]$$
(14.9)

$$p = e^{-rT}[KN(-d_2) - F_0N(-d_1)]$$
(14.10)

where

$$d_1 = \frac{\ln(F_0/K) + \sigma^2 T/2}{\sigma\sqrt{T}}$$

$$d_2 = \frac{\ln(F_0/K) - \sigma^2 T/2}{\sigma\sqrt{T}} = d_1 - \sigma\sqrt{T}$$

Note that, for equations (14.9) and (14.10), to be the correct equations for valuing a European option on the spot foreign exchange rate, the maturities of the forward contract and the option must be the same.

## **Binomial Trees**

In some circumstances it is optimal to exercise American currency options prior to maturity. Thus, American currency options are worth more than their European counterparts. In general, call options on high-interest currencies and put options on

low-interest currencies are the most likely to be exercised prior to maturity. The reason is that a high-interest currency is expected to depreciate and a low-interest currency is expected to appreciate. Binomial trees can be used to value American-style currency options as described in Section 11.9. An example of the valuation of a currency option is given in Example 11.2 and Figure 11.12.

#### 14.5 FUTURES OPTIONS

Options on futures contracts, or futures options, are now traded on many different exchanges. They are American-style options and require the delivery of an underlying futures contract when exercised. If a call futures option is exercised, the holder acquires a long position in the underlying futures contract plus a cash amount equal to the most recent settlement futures price minus the strike price. If a put futures option is exercised, the holder acquires a short position in the underlying futures contract plus a cash amount equal to the strike price minus the most recent settlement futures price. As the following examples show, the effective payoff from a call futures option is the futures price at the time of exercise less the strike price; the effective payoff from a put futures option is the strike price less the futures price at the time of exercise.

#### Example 14.3

Suppose it is August 15 and an investor has one September futures call option contract on copper with a strike price of 70 cents per pound. One futures contract is on 25,000 pounds of copper. Suppose that the futures price of copper for delivery in September is currently 81 cents, and at the close of trading on August 14 (the last settlement) it was 80 cents. If the option is exercised, the investor receives a cash amount of

$$25,000 \times (80 - 70) \text{ cents} = \$2,500$$

plus a long position in a futures contract to buy 25,000 pounds of copper in September. If desired, the position in the futures contract can be closed out immediately. This would leave the investor with the \$2,500 cash payoff plus an amount

$$25,000 \times (81 - 80) \text{ cents} = \$250$$

reflecting the change in the futures price since the last settlement. The total payoff from exercising the option on August 15 is \$2,750, which equals 25,000(F-K), where F is the futures price at the time of exercise and K is the strike price.

#### Example 14.4

An investor has one December futures put option on corn with a strike price of 200 cents per bushel. One futures contract is on 5,000 bushels of corn. Suppose that the current futures price of corn for delivery in December is 180, and the most recent settlement price is 179 cents. If the option is exercised, the investor receives a cash amount of

$$5,000 \times (200 - 179) \text{ cents} = \$1,050$$

plus a short position in a futures contract to sell 5,000 bushels of corn in December.

If desired, the position in the futures contract can be closed out. This would leave the investor with the \$1,050 cash payoff minus an amount

$$5,000 \times (180 - 179) \text{ cents} = $50$$

reflecting the change in the futures price since the last settlement. The net payoff from exercise is \$1,000, which equals 5,000(K-F), where F is the futures price at the time of exercise and K is the strike price.

## Quotes'

Futures options are referred to by the month in which the underlying futures contract matures—not by the expiration month of the option. As mentioned earlier, futures options are American. The expiration date of a futures option contract is usually on, or a few days before, the earliest delivery date of the underlying futures contract. (For example, the CBOT Treasury bond futures option expires on the Friday preceding by at least two business days the end of the month before the futures contract expiration month.) An exception is the CME mid-curve Eurodollar contract, where the futures contract expires either one or two years after the options contract.

Table 14.4 shows quotes for futures options as they appeared in the *Wall Street Journal* on February 5, 2004. The most popular contracts (as measured by open interest) are those on corn, soybeans, cotton, sugar-world, crude oil, natural gas, gold, Treasury bonds, Treasury notes, 5-year Treasury notes, 30-day federal funds, Eurodollars, 1-year and 2-year mid-curve Eurodollars, Euribor, Eurobunds, and the S&P 500.

## **Options on Interest Rate Futures**

The most actively traded interest rate options offered by exchanges in the United States are those on Treasury bond futures, Treasury note futures, and Eurodollar futures. Table 14.4 shows the closing prices for these instruments on February 4, 2004.

A Treasury bond futures option is an option to enter a Treasury bond futures contract. As mentioned in Chapter 6, one Treasury bond futures contract is for the delivery of \$100,000 of Treasury bonds. The price of a Treasury bond futures option is quoted as a percentage of the face value of the underlying Treasury bonds to the nearest sixty-fourth of 1%. Table 14.4 gives the price of the March call futures option on a Treasury bond on February 4, 2004, as 2-06, or  $2\frac{6}{64}$ % of the bond principal, when the strike price is 110. This means that one contract costs \$2,093.75. The quotes for options on Treasury notes are similar.

An option on Eurodollar futures is an option to enter into a Eurodollar futures contract. As explained in Chapter 6, when the Eurodollar futures quote changes by 1 basis point, or 0.01%, there is a gain or loss on a Eurodollar futures contract of \$25. Similarly, in the pricing of options on Eurodollar futures, 1 basis point represents \$25. The *Wall Street Journal* quote for the CME Eurodollar futures contract in Table 14.4 should be multiplied by 10 to get the CME quote in basis points. For example, the 5.90 quote for the CME March call futures option when the strike price is 98.25 in Table 14.4 indicates that the CME quote is 59.0 basis points and one contract costs  $59.0 \times $25 = $1,475.00$ .

Interest rate futures option contracts work in the same way as the other futures options contracts discussed in this chapter. For example, the payoff from a call is  $\max(F - K, 0)$ , where F is the futures price at the time of exercise and K is the strike price. In addition to the cash payoff, the option holder obtains a long position in the futures contract when the option is exercised and the option writer obtains a corresponding short position.

Interest rate futures prices increase when bond prices increase (i.e., when interest rates fall). They decrease when bond prices decrease (i.e., when interest rates rise). An investor who thinks that short-term interest rates will rise can speculate by buying put options on Eurodollar futures, whereas an investor who thinks the rates will fall can speculate by buying call options on Eurodollar futures. An investor who thinks that long-term interest rates will rise can speculate by buying put options on Treasury note futures or Treasury bond futures, whereas an investor who thinks the rates will fall can speculate by buying call options on these instruments.

#### Example 14.5

It is February and the futures price for the June Eurodollar contract is 93.82 (corresponding to a 3-month Eurodollar interest rate of 6.18% per annum). The price of a call option on the contract with a strike price of 94.00 is quoted at the CME as 0.1, or 10 basis points (corresponding to a *Wall Street Journal* quote of 1.00). This option could be attractive to an investor who feels that interest rates are likely to come down. Suppose that short-term interest rates do drop by about 100 basis points and the investor exercises the call when the Eurodollar futures price is 94.78 (corresponding to a 3-month Eurodollar interest rate of 5.22% per annum). The payoff is  $25 \times (94.78 - 94.00) = \$1,950$ . The cost of the contract is  $10 \times 25 = \$250$ . The investor's profit is therefore \$1,700.

## Example 14.6

It is August and the futures price for the December Treasury bond contract traded on the CBOT is 96-09 (or  $96\frac{9}{32} = 96.28125$ ). The yield on long-term government bonds is about 6.4% per annum. An investor who feels that this yield will fall by December might choose to buy December calls with a strike price of 98. Assume that the price of these calls is 1-04 (or  $1\frac{4}{64} = 1.0625\%$  of the principal). If long-term rates fall to 6% per annum and the Treasury bond futures price rises to 100-00, the investor will make a net profit per \$100 of bond futures of

$$100.00 - 98.00 - 1.0625 = 0.9375$$

Since one option contract is for the purchase or sale of instruments with a face value of \$100,000, the investor would make a profit of \$937.50 per option contract bought.

## Reasons for the Popularity of Futures Options

It is natural to ask why people choose to trade options on futures rather than options on the underlying asset. The main reason appears to be that a futures contract is, in many circumstances, more liquid and easier to trade than the underlying asset. Furthermore, a futures price is known immediately from trading on the futures exchange, whereas the spot price of the underlying asset may not be so readily available.

Consider Treasury bonds. The market for Treasury bond futures is much more active than the market for any particular Treasury bond. Moreover, a Treasury bond futures price is known immediately from trading on the CBOT. By contrast, the current market price of a bond can be obtained only by contacting one or more dealers. It is not surprising that investors would rather take delivery of a Treasury bond futures contract than Treasury bonds.

Futures on commodities are also often easier to trade than the commodities themselves. For example, it is much easier and more convenient to make or take delivery of a live-hogs futures contract than it is to make or take delivery of the hogs themselves.

An important point about a futures option is that exercising it does not usually lead to delivery of the underlying asset. This is because, in most circumstances, the underlying futures contract is closed out prior to delivery. Futures options are therefore normally eventually settled in cash. This is appealing to many investors, particularly those with limited capital who may find it difficult to come up with the funds to buy the underlying asset when an option is exercised.

Another advantage sometimes cited for futures options is that futures and futures options are traded in pits side by side in the same exchange. This facilitates hedging, arbitrage, and speculation. It also tends to make the markets more efficient.

A final point is that futures options tend to entail lower transactions costs than spot options in many situations.

## **Put-Call Parity**

In Chapter 9, we derived a put—call parity relationship for European stock options. We now present a similar argument to derive a put—call parity relationship for European futures options on the assumption that there is no difference between the payoffs from futures and forward contracts.

Consider European call and put futures options, both with strike price K and time to expiration T. We can form two portfolios:

Portfolio A: a European call futures option plus an amount of cash equal to  $Ke^{-rT}$ 

Portfolio B: a European put futures option plus a long futures contract plus an amount of cash equal to  $F_0e^{-rT}$ 

In portfolio A, the cash can be invested at the risk-free rate r and will grow to K at time T. Let  $F_T$  be the futures price at maturity of the option. If  $F_T > K$ , the call option in portfolio A is exercised and portfolio A is worth  $F_T$ . If  $F_T \leq K$ , the call is not exercised and portfolio A is worth K. The value of portfolio A at time T is therefore given by

$$\max(F_T, K)$$

In portfolio B, the cash can be invested at the risk-free rate to grow to  $F_0$  at time T. The put option provides a payoff of  $\max(K - F_T, 0)$ . The futures contract provides a payoff of  $F_T - F_0$ . The value of portfolio B at time T is therefore given by

$$F_0 + (F_T - F_0) + \max(K - F_T, 0) = \max(F_T, K)$$

Since the two portfolios have the same value at time T and there are no early exercise

opportunities, it follows that they are worth the same today. The value of portfolio A today is

$$c + Ke^{-rT}$$

where c is the price of the call futures option. The marking-to-market process ensures that the futures contract in portfolio B is worth zero today. Therefore, portfolio B is worth

$$p + F_0 e^{-rT}$$

where p is the price of the put futures option. Hence,

$$c + Ke^{-rT} = p + F_0e^{-rT} (14.11)$$

This is the same as put-call parity for options on a non-dividend-paying stock in equation (9.3) except that the stock price is replaced by the futures price times  $e^{-rT}$  For American options, the put-call parity relationship is (see Problem 14.38)

$$F_0e^{-rT}-K\leqslant C-P\leqslant F_0-Ke^{-rT}$$

#### Example 14.7

Suppose that the price of a European call option on silver futures for delivery in 6 months is \$0.56 per ounce when the exercise price is \$8.50. Assume that the silver futures price for delivery in 6 months is currently \$8.00 and the risk-free interest rate for an investment that matures in 6 months is 10% per annum. From a rearrangement of equation (14.11), the price of a European put option on silver futures with the same maturity and exercise price as the call option is

$$0.56 + 8.50e^{-0.1 \times 0.5} - 8.00e^{-0.1 \times 0.5} = 1.04$$

## 14.6 VALUATION OF FUTURES OPTIONS USING BINOMIAL TREES

This section examines, more formally than in Chapter 11, how binomial trees can be used to price futures options. The key difference between futures options and stock options is that there are no up-front costs when a futures contract is entered into.

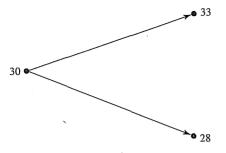

Suppose that the current futures price is 30 and it is expected to move either up to 33 or down to 28 over the next month. We consider a 1-month call option on the futures with a strike price of 29 and ignore daily settlement. The situation is shown in Figure 14.1. If the futures price proves to be 33, then the payoff from the option is 4 and the value of the futures contract is 3. If the futures price proves to be 28, then the payoff from the option is zero and the value of the futures contract is -2.

To set up a riskless hedge, we consider a portfolio consisting of a short position in one option contract and a long position in  $\Delta$  futures contracts. If the futures price moves up to 33, the value of the portfolio is  $3\Delta - 4$ ; if it moves down to 28, the value of the portfolio is  $-2\Delta$ . The portfolio is riskless when these are the same—that is,

 $<sup>^{3}</sup>$  There is an approximation here in that the gain or loss on the futures contract is not realized at time T. It is realized day by day between time 0 and time T. However, as the length of the time step in a binomial tree becomes shorter, the approximation becomes better, and in the limit, as the time step tends to zero, an accurate answer is obtained.

330 CHAPTER 14

Figure 14.1 Futures price movements in numerical example.

when

$$3\Delta - 4 = -2\Delta$$

or 
$$\Delta = 0.8$$
.

For this value of  $\Delta$ , we know the portfolio will be worth  $3 \times 0.8 - 4 = -1.6$  in 1 month. Assume a risk-free interest rate of 6%. The value of the portfolio today must be

$$-1.6e^{-0.06\times0.08333} = -1.592$$

The portfolio consists of one short option and  $\Delta$  futures contracts. Since the value of the futures contract today is zero, the value of the option today must be 1.592.

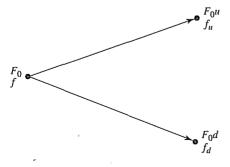

#### A Generalization

We can generalize this analysis by considering a futures price that starts at  $F_0$  and is anticipated to rise to  $F_0u$  or move down to  $F_0d$  over the time period T. We consider a derivative maturing at the end of the time period, and we suppose that its payoff is  $f_u$  if the futures price moves up and  $f_d$  if it moves down. The situation is summarized in Figure 14.2.

The riskless portfolio in this case consists of a short position in one option combined with a long position in  $\Delta$  futures contracts, where

$$\Delta = \frac{f_u - f_d}{F_0 u - F_0 d}$$

Figure 14.2 Futures price and option price in general situation.

The value of the portfolio at the end of the time period, then, is always

$$(F_0u-F_0)\Delta-f_u$$

Denoting the risk-free interest rate by r, we obtain the value of the portfolio today as

$$[(F_0u-F_0)\Delta-f_u]e^{-rT}$$

Another expression for the present value of the portfolio is -f, where f is the value of the option today. It follows that

$$-f = [(F_0u - F_0)\Delta - f_u]e^{-rT}$$

Substituting for  $\Delta$  and simplifying reduces this equation to

$$f = e^{-rT}[pf_u + (1-p)f_d]$$
 (14.12)

where

$$p = \frac{1 - d}{u - d} \tag{14.13}$$

In the numerical example in Figure 14.1, u = 1.1, d = 0.9333, r = 0.06, T = 0.08333,  $f_u = 4$ , and  $f_d = 0$ . From equation (14.13), we have

$$p = \frac{1 - 0.9333}{1.1 - 0.9333} = 0.4$$

and, from equation (14.12),

$$f = e^{-0.06 \times 0.08333} (0.4 \times 4 + 0.6 \times 0) = 1.592$$

This result agrees with the answer obtained for this example earlier.

## **Multistep Trees**

In practice, trees are used to value American-style futures options in the same way as they are used to value options on stocks. This is explained in Section 11.9. An example is in Example 11.3 and Figure 11.13.

#### 14.7 THE DRIFT OF FUTURES PRICES IN A RISK-NEUTRAL WORLD

There is a general result that allows us to use the analysis in Section 14.1 for futures options. This result is that in a risk-neutral world a futures price behaves in the same way as a stock paying a dividend yield at the domestic risk-free interest rate r.

One clue that this might be so is given by noting that the equation for p in a binomial tree for a futures price is the same as that for a stock paying a dividend yield equal to q when q=r. Another clue is that the put-call parity relationship for futures options prices is the same as that for options on a stock paying a dividend yield at rate q when the stock price is replaced by the futures price and q=r.

To prove the result formally, we calculate the drift of a futures price in a risk-neutral world. We define  $F_t$  as the futures price at time t. If we enter into a long futures contract today, its value is zero. At time  $\Delta t$  (the first time it is marked to market) it provides a payoff of  $F_{\Delta t} - F_0$ . If r is the very-short-term ( $\Delta t$ -period) interest rate at

time 0, risk-neutral valuation gives the value of the contract at time 0 as

$$e^{-r\Delta t}\hat{E}[F_{\Delta t}-F_0]$$

where  $\hat{E}$  denotes expectations in a risk-neutral world. We must therefore have

$$e^{-r\Delta t}\hat{E}(F_{\Delta t}-F_0)=0$$

showing that

$$\hat{E}(F_{\Delta t}) = F_0$$

Similarly,  $\hat{E}(F_{2\Delta t}) = F_{\Delta t}$ ,  $\hat{E}(F_{3\Delta t}) = F_{2\Delta t}$ , and so on. Putting many results like this together, we see that

$$\hat{E}(F_T) = F_0$$

for any time T

The drift of the futures price in a risk-neutral world is therefore zero. From equation (14.7), then, the futures price behaves like a stock providing a dividend yield q equal to r. This result is a very general one. It is true for all futures prices and does not depend on any assumptions about interest rates, volatilities, etc.<sup>4</sup>

The usual assumption made for the process followed by a futures price F in the risk-neutral world is

$$dF = \sigma F dz \tag{14.14}$$

where  $\sigma$  is a constant.

## **Differential Equation**

For another way of seeing that a futures price behaves like a stock paying a dividend yield at rate q, we can derive the differential equation satisfied by a derivative dependent on a futures price in the same way as we derived the differential equation for a derivative dependent on a non-dividend-paying stock in Section 13.6. This is  $^{5}$ 

$$\frac{\partial f}{\partial t} + \frac{1}{2} \frac{\partial^2 f}{\partial F^2} \sigma^2 F^2 = rf \tag{14.15}$$

It has the same form as equation (14.6) with q set equal to r. This confirms that, for the purpose of valuing derivatives, a futures price can be treated in the same way as a stock providing a dividend yield at rate r.

## 14.8 BLACK'S MODEL FOR VALUING FUTURES OPTIONS

European futures options can be valued by extending the results we have produced. Fischer Black was the first to show this in a paper published in 1976. The underlying

 $<sup>^4</sup>$  As we will discover in Chapter 25, a more precise statement of the result is: "A futures price has zero drift in the traditional risk-neutral world where the numeraire is the money market account." A zero-drift stochastic process is known as a martingale. A forward price is a martingale in a different risk-neutral world. This is one where the numeraire is a zero-coupon bond maturing at time T.

<sup>&</sup>lt;sup>5</sup> See Technical Note 7 on the author's website for a proof of this.

<sup>&</sup>lt;sup>6</sup> See F. Black, "The Pricing of Commodity Contracts," *Journal of Financial Economics*, 3 (March 1976): 167-79.

assumption is that futures prices have the same lognormal property that we assumed for stock prices in Chapter 13. The European call price c and the European put price p for a futures option are given by equations (14.4) and (14.5) with  $S_0$  replaced by  $F_0$  and q = r:

$$c = e^{-rT}[F_0N(d_1) - KN(d_2)]$$
(14.16)

$$p = e^{-rT}[KN(-d_2) - F_0N(-d_1)]$$
(14.17)

where

$$d_1 = \frac{\ln(F_0/K) + \sigma^2 T/2}{\sigma\sqrt{T}}$$

$$d_2 = \frac{\ln(F_0/K) - \sigma^2 T/2}{\sigma\sqrt{T}} = d_1 - \sigma\sqrt{T}$$

and  $\sigma$  is the volatility of the futures price. When the cost of carry and the convenience yield are functions only of time, it can be shown that the volatility of the futures price is the same as the volatility of the underlying asset. Note that Black's model does not require the option contract and the futures contract to mature at the same time.

#### Example 14.8

Consider a European put futures option on crude oil. The time to the option's maturity is 4 months, the current futures price is \$20, the exercise price is \$20, the risk-free interest rate is 9% per annum, and the volatility of the futures price is 25% per annum. In this case,  $F_0 = 20$ , K = 20, r = 0.09, T = 4/12,  $\sigma = 0.25$ , and  $\ln(F_0/K) = 0$ , so that

$$d_1 = \frac{\sigma\sqrt{T}}{2} = 0.07216$$

$$d_2 = -\frac{\sigma\sqrt{T}}{2} = -0.07216$$

$$N(-d_1) = 0.4712, \qquad N(-d_2) = 0.5288$$

and the put price p is given by

$$p = e^{-0.09 \times 4/12} (20 \times 0.5288 - 20 \times 0.4712) = 1.12$$
 or \$1.12.

#### 14.9 FUTURES OPTIONS vs. SPOT OPTIONS

In this section we compare options on futures and options on spot when they have the same strike price and time to maturity. An *option on spot* or *spot option* is a regular option to buy or sell the underlying asset in the spot market.

The payoff from a European spot call option with strike price K is

$$\max(S_T - K, 0)$$

where  $S_T$  is the spot price at the option's maturity. The payoff from a European futures call option with the same strike price is

$$\max(F_T - K, 0)$$

334 CHAPTER 14

where  $F_T$  is the futures price at the option's maturity. If the European futures option matures at the same time as the futures contract,  $F_T = S_T$  and the two options are in theory equivalent. If the European call futures option matures before the futures contract, it is worth more than the corresponding spot option in a normal market (where futures prices are higher than spot prices) and less than the corresponding spot option in an inverted market (where futures prices are lower than spot prices).

Similarly, a European futures put option is worth the same as its spot option counterpart when the futures option matures at the same time as the futures contract. If the European put futures option matures before the futures contract, it is worth less than the corresponding spot option in a normal market and more than the corresponding spot option in an inverted market.

## **Results for American Options**

Traded futures options are, in practice, usually American. Assuming that the risk-free rate of interest, r, is positive, there is always some chance that it will be optimal to exercise an American futures option early. American futures options are, therefore, worth more than their European counterparts.

It is not generally true that an American futures option is worth the same as the corresponding American spot option when the futures and options contracts have the same maturity. Suppose, for example, that there is a normal market with futures prices consistently higher than spot prices prior to maturity. This is the case with most stock indices, gold, silver, low-interest currencies, and some commodities. An American call futures option must be worth more than the corresponding American spot call option. The reason is that in some situations the futures option will be exercised early, in which case it will provide a greater profit to the holder. Similarly, an American put futures option must be worth less than the corresponding American spot put option. If there is an inverted market with futures prices consistently lower than spot prices, as is the case with high-interest currencies and some commodities, the reverse must be true. American call futures options are worth less than the corresponding American spot call option, whereas American put futures options are worth more than the corresponding American spot put option.

The differences just described between American futures options and American spot options hold true when the futures contract expires later than the options contract as well as when the two expire at the same time. In fact, the differences tend to be greater the later the futures contract expires.

#### **SUMMARY**

The Black-Scholes formula for valuing European options on a non-dividend-paying stock can be extended to cover European options on a stock providing a known dividend yield. This is a useful result because a number of other assets on which options are written can be considered to be analogous to a stock providing a dividend yield. In particular:

1. An index is analogous to a stock providing a dividend yield. The dividend yield is the average dividend yield on the stocks composing the index.

- 2. A foreign currency is analogous to a stock providing a dividend yield where the dividend yield is the foreign risk-free interest rate.
- 3. A futures price is analogous to a stock providing a dividend yield where the dividend yield is equal to the domestic risk-free interest rate.

The extension to Black-Scholes can, therefore, be used to value European options on indices, foreign currencies, and futures contracts.

Index options are settled in cash. Upon exercise of an index call option, the holder receives the amount by which the index exceeds the strike price at close of trading. Similarly, upon exercise of an index put option, the holder receives the amount by which the strike price exceeds the index at close of trading. Index options can be used for portfolio insurance. If the portfolio has a  $\beta$  of 1.0, it is appropriate to buy one put option for each  $100S_0$  dollars in the portfolio, where  $S_0$  is the value of the index; otherwise,  $\beta$  put options should be purchased for each  $100S_0$  dollars in the portfolio, where  $\beta$  is the beta of the portfolio calculated using the capital asset pricing model. The strike price of the put options purchased should reflect the level of insurance required.

Currency options are traded both on organized exchanges and over the counter. They can be used by corporate treasurers to hedge foreign exchange exposure. For example, a US corporate treasurer who knows that sterling will be received at a certain time in the future can hedge by buying put options that mature at that time. Similarly, a US corporate treasurer who knows that the company will be paying sterling at a certain time in the future can hedge by buying call options that mature at that time.

Futures options require the delivery of the underlying futures contract upon exercise. When a call is exercised, the holder acquires a long futures position plus a cash amount equal to the excess of the futures price over the strike price. Similarly, when a put is exercised, the holder acquires a short position plus a cash amount equal to the excess of the strike price over the futures price. The futures contract that is delivered typically expires slightly later than the option. If we assume that the two expiration dates are the same, a European futures option is worth exactly the same as the corresponding European spot option. However, this is not true of American options. If the futures market is normal, an American call futures option is worth more than the corresponding American spot call option, while an American put futures is worth less than the corresponding American spot put option. If the futures market is inverted, the reverse is true.

## **Questions and Problems (Answers in Solutions Manual)**

- 14.1. A portfolio is currently worth \$10 million and has a beta of 1.0. The S&P 100 is currently standing at 500. Explain how a put option on the S&P 100 with a strike of 480 can be used to provide portfolio insurance.
- 14.2. "Once we know how to value options on a stock paying a dividend yield, we know how to value options on stock indices, currencies, and futures." Explain this statement.
- 14.3. A stock index is currently 300, the dividend yield on the index is 3% per annum, and the risk-free interest rate is 8% per annum. What is a lower bound for the price of a 6-month European call option on the index when the strike price is 290?
- 14.4. A currency is currently worth \$0.80. Over each of the next 2 months it is expected to increase or decrease in value by 2%. The domestic and foreign risk-free interest rates are 6% and 8%, respectively. What is the value of a 2-month European call option with a strike price of \$0.80?
- 14.5. Explain the difference between a call option on yen and a call option on yen futures.
- 14.6. Explain how currency options can be used for hedging.
- 14.7. Calculate the value of a 3-month at-the-money European call option on a stock index when the index is at 250, the risk-free interest rate is 10% per annum, the volatility of the index is 18% per annum, and the dividend yield on the index is 3% per annum.
- 14.8. Consider an American call futures option where the futures contract and the option contract expire at the same time. Under what circumstances is the futures option worth more than the corresponding American option on the underlying asset?
- 14.9. Calculate the value of an 8-month European put option on a currency with a strike price of 0.50. The current exchange rate is 0.52, the volatility of the exchange rate is 12%, the domestic risk-free interest rate is 4% per annum, and the foreign risk-free interest rate is 8% per annum.
- 14.10. Why are options on bond futures more actively traded than options on bonds?

- 14.11. "A futures price is like a stock paying a dividend yield." What is the dividend yield?
- 14.12. A futures price is currently 50. At the end of 6 months it will be either 56 or 46. The risk-free interest rate is 6% per annum. What is the value of a 6-month European call option with a strike price of 50?
- 14.13. Calculate the value of a 5-month European put futures option when the futures price is \$19, the strike price is \$20, the risk-free interest rate is 12% per annum, and the volatility of the futures price is 20% per annum.
- 14.14. A total return index tracks the return, including dividends, on a certain portfolio. Explain how you would value (a) forward contracts and (b) European options on the index.
- 14.15. The S&P 100 index currently stands at 696 and has a volatility of 30% per annum. The risk-free rate of interest is 7% per annum and the index provides a dividend yield of 4% per annum. Calculate the value of a 3-month European put with strike price 700.
- 14.16. What is the put-call parity relationship for European currency options?
- 14.17. A foreign currency is currently worth \$1.50. The domestic and foreign risk-free interest rates are 5% and 9%, respectively. Calculate a lower bound for the value of a 6-month call option on the currency with a strike price of \$1.40 if it is (a) European and (b) American.
- 14.18. Consider a stock index currently standing at 250. The dividend yield on the index is 4% per annum and the risk-free rate is 6% per annum. A 3-month European call option on the index with a strike price of 245 is currently worth \$10. What is the value of a 3-month European put option on the index with a strike price of 245?
- 14.19. Would you expect the volatility of a stock index to be greater or less than the volatility of a typical stock? Explain your answer.
- 14.20. Does the cost of portfolio insurance increase or decrease as the beta of the portfolio increases? Explain your answer.
- 14.21. Suppose that a portfolio is worth \$60 million and the S&P 500 is at 1200. If the value of the portfolio mirrors the value of the index, what options should be purchased to provide protection against the value of the portfolio falling below \$54 million in 1 year's time?
- 14.22. Consider again the situation in Problem 14.21. Suppose that the portfolio has a beta of 2.0, that the risk-free interest rate is 5% per annum, and that the dividend yield on both the portfolio and the index is 3% per annum. What options should be purchased to provide protection against the value of the portfolio falling below \$54 million in 1 year's time?
- 14.23. Suppose you buy a put option contract on October gold futures with a strike price of \$400 per ounce. Each contract is for the delivery of 100 ounces. What happens if you exercise when the October futures price is \$377 and the most recent settlement price is \$380?
- 14.24. Suppose you sell a call option contract on April live-cattle futures with a strike price of 70 cents per pound. Each contract is for the delivery of 40,000 pounds. What happens if the contract is exercised when the futures price is 76 cents and the most recent settlement price is 75 cents?
- 14.25. Consider a 2-month call futures option with a strike price of 40 when the risk-free interest rate is 10% per annum. The current futures price is 47. What is a lower bound for the value of the futures option if it is (a) European and (b) American?

338 CHAPTER 14

14.26. Consider a 4-month put futures option with a strike price of 50 when the risk-free interest rate is 10% per annum. The current futures price is 47. What is a lower bound for the value of the futures option if it is (a) European and (b) American?

- 14.27. A futures price is currently 60. It is known that over each of the next two 3-month periods it will either rise by 10% or fall by 10%. The risk-free interest rate is 8% per annum. What is the value of a 6-month European call option on the futures with a strike price of 60? If the call were American, would it ever be worth exercising it early?
- 14.28. In Problem 14.27, what is the value of a 6-month European put option on futures with a strike price of 60? If the put were American, would it ever be worth exercising it early? Verify that the call prices calculated in Problem 14.27 and the put prices calculated here satisfy put—call parity relationships.
- 14.29. A futures price is currently 25, its volatility is 30% per annum, and the risk-free interest rate is 10% per annum. What is the value of a 9-month European call on the futures with a strike price of 26?
- 14.30. A futures price is currently 70, its volatility is 20% per annum, and the risk-free interest rate is 6% per annum. What is the value of a 5-month European put on the futures with a strike price of 65?
- 14.31. Suppose that a futures price is currently 35. A European call option and a European put option on the futures with a strike price of 34 are both priced at 2 in the market. The risk-free interest rate is 10% per annum. Identify an arbitrage opportunity. Both options have 1 year to maturity.
- 14.32. "The price of an at-the-money European call futures option always equals the price of a similar at-the-money European put futures option." Explain why this statement is true.
- 14.33. Suppose that a futures price is currently 30. The risk-free interest rate is 5% per annum. A 3-month American call futures option with a strike price of 28 is worth 4. Calculate bounds for the price of a 3-month American put futures option with a strike price of 28.
- 14.34. Can an option on the yen/euro exchange rate be created from two options, one on the dollar/euro exchange rate, and the other on the dollar-yen exchange rate? Explain your answer.
- 14.35. A corporation knows that in 3 months it will have \$5 million to invest for 90 days at LIBOR minus 50 basis points and wishes to ensure that the rate obtained will be at least 6.5%. What position in exchange-traded interest rate options should it take?
- 14.36. Prove the results in equations (14.1), (14.2), and (14.3) using the following portfolios:

Portfolio A: one European call option plus an amount of cash equal to  $Ke^{-rT}$ 

Portfolio B:  $e^{-qT}$  shares, with dividends being reinvested in additional shares

Portfolio C: one European put option plus  $e^{-qT}$  shares, with dividends on the shares being reinvested in additional shares

Portfolio D: an amount of cash equal to  $Ke^{-rT}$ 

14.37. Show that, if C is the price of an American call with strike price K and maturity T on a stock providing a dividend yield of q, and P is the price of an American put on the same stock with the same strike price and exercise date, then

$$S_0 e^{-qT} - K \leqslant C - P \leqslant S_0 - K e^{-rT}$$

where  $S_0$  is the stock price, r is the risk-free interest rate, and r > 0. (Hint: To obtain the

first half of the inequality, consider possible values of:

Portfolio A: a European call option plus an amount K invested at the risk-free rate Portfolio B: an American put option plus  $e^{-qT}$  of stock with dividends being reinvested in the stock

To obtain the second half of the inequality, consider possible values of:

Portfolio C: an American call option plus an amount  $Ke^{-rT}$  invested at the risk-free rate Portfolio D: a European put option plus one stock, with dividends being reinvested in the stock.)

14.38. Show that, if C is the price of an American call option on a futures contract when the strike price is K and the maturity is T, and P is the price of an American put on the same futures contract with the same strike price and exercise date, then

$$F_0e^{-rT} - K \leqslant C - P \leqslant F_0 - Ke^{-rT}$$

where  $F_0$  is the futures price and r is the risk-free rate. Assume that r > 0 and that there is no difference between forward and futures contracts. (*Hint*: Use an analogous approach to that indicated for Problem 14.37.)

14.39. If the price of currency A expressed in terms of the price of currency B follows the process  $dS = (r_B - r_A)S dt + \sigma S dz$ 

where  $r_A$  is the risk-free interest rate in currency A and  $r_B$  is the risk-free interest rate in currency B. What is the process followed by the price of currency B expressed in terms of currency A?

## **Assignment Questions**

- 14.40. Use the DerivaGem software to calculate implied volatilities for the March 104 call and the March 104 put on the Dow Jones Industrial Average (DJX) in Table 14.1. The value of the DJX on February 4, 2004, was 104.71. Assume that the risk-free rate was 1.2% and that the dividend yield was 3.5%. The options expire on March 20, 2004. Are the quotes for the two options consistent with put—call parity?
- 14.41. A stock index currently stands at 300. It is expected to increase or decrease by 10% over each of the next two time periods of 3 months. The risk-free interest rate is 8% and the dividend yield on the index is 3%. What is the value of a 6-month put option on the index with a strike price of 300 if it is (a) European and (b) American?
- 14.42. Suppose that the spot price of the Canadian dollar is US \$0.75 and that the Canadian dollar/US dollar exchange rate has a volatility of 4% per annum. The risk-free rates of interest in Canada and the United States are 9% and 7% per annum, respectively. Calculate the value of a European call option to buy one Canadian dollar for US \$0.75 in 9 months. Use put—call parity to calculate the price of a European put option to sell one Canadian dollar for US \$0.75 in 9 months. What is the price of a call option to buy US \$0.75 with one Canadian dollar in 9 months?
- 14.43. A mutual fund announces that the salaries of its fund managers will depend on the performance of the fund. If the fund loses money, the salaries will be zero. If the fund makes a profit, the salaries will be proportional to the profit. Describe the salary of a fund manager as an option. How is a fund manager motivated to behave with this type of remuneration package?

340 CHAPTER 14

14.44. A futures price is currently 40. It is known that at the end of 3 months the price will be either 35 or 45. What is the value of a 3-month European call option on the futures with a strike price of 42 if the risk-free interest rate is 7% per annum?

14.45. Calculate the implied volatility of soybean futures prices from the following information concerning a European put on soybean futures:

Current futures price	525
Exercise price	525
Risk-free rate	6% per annum
Time to maturity	5 months
Put price	20

14.46. Use the DerivaGem software to calculate implied volatilities for the July options on corn futures in Table 14.4. Assume the futures prices in Table 2.2 apply and that the risk-free rate is 1.1% per annum. Treat the options as American and use 100 time steps. The options mature on June 19, 2004. Can you draw any conclusions from the pattern of implied volatilities you obtain?
